

## REMARKS

The present invention is a method of operating electrical circuitry included in a user exchangeable cover part for supporting a user interface of a wireless terminal; a wireless communication terminal including an user exchangeable cover part; and an user exchangeable cover for releasable attachment to a wireless communication terminal. In accordance with an embodiment of the invention, a method of operating electrical circuitry 46 illustrated in Fig. 3 included in an user exchangeable cover part 25 also including a keyboard 2 and a display 3 for supporting a user interface 2, 3, 5 and 6 of a wireless terminal, the wireless communication terminal and the user exchangeable cover part being electrically connected by means of an electrical connector 41, 42, and 44 comprises identifying a type of user exchangeable cover part; and operating the electrical circuitry of the user exchangeable cover part in dependence upon the identification of the user exchangeable cover part.

Claims 1-2, 4, 5, 9 and 11 stand rejected under 35 U.S.C. §102 as being anticipated by United States Patent 5,911,121 (Andrews). These grounds of rejection are traversed with respect to corresponding claims 12, 13, 15, 16, 20 and 22 for the following reasons.

Andrews discloses mobile radio communication devices which include different keypads 18 and displays 20 and associated software options which are designed to operate with respect to a common printed circuit board architecture. See column 3, lines 17-40 of Andrews. The cover part 44 of Andrews includes a program selector 60 which is sensed by a detection circuit located in the printed circuit board 46. Moreover, the printed circuit board 46

contains the operative electronics including a microprocessor 12. The architectural description of the telephone of Figure 1 clearly states that the "[t]he mobile phone includes 10 includes a microprocessor 12 for controlling the operation of the mobile telephone 10 in a program memory 14 for storing programs used by the mobile telephone 10". The detection circuit 50 generates a configuration signal or signals representing the program configuration to be used by microprocessor 12 which corresponds to a particular model mobile telephone 10. See column 3, lines 53-57 of Andrews. The keypad 18 and display 20 are part of a removable cover part.

Each of the independent claims recites in substance that the electrical circuitry of the user exchangeable cover part, other than the key board and display, is operated in dependence upon the identification of the user exchangeable cover part. However, with Andrews what occurs is that the identification of the cover part causes the microprocessor 12 and the memory 14 to control the functions which are dependent upon the identification of the cover part. However, there is no description of operation of electrical circuitry of the user exchangeable cover part in Andrews, exclusive of the key board and display, being operated in dependence upon the identification of the user exchangeable cover part. Since the independent claims recite the combination of a key board, display and electrical circuitry, there is no counterpart of the electrical circuitry in Andrews.

Accordingly, it is submitted that independent claims 1, 4 and 11 in corresponding new claims 12, 15 and 22 are not anticipated by Andrews.

Claim 13 further limits claim 12 in reciting that the connector has a plurality of pins and at least one of the connector pins is operated in an

identification state for sensing a resistor value included in an identification means of the user exchangeable cover part and afterwards is operated in an operation state operating the electrical circuitry of the user exchangeable part. Andrews et al. relies upon the resistance values which are part of the circuit board 46 as may be seen from the reference numerals 52 in Fig. 2 and Fig. 4. Accordingly, claim 13 is not anticipated.

Claim 16 is patentable for the same reasons set forth above with respect to claim 15.

Claim 20 further limits claim 16 in reciting at least one of the connector pins is operated in an identification state for sensing the resistor value included in the identification means, and afterwards is operated in an operation state operating the electrical circuitry of the user exchangeable cover part. Claim 20 is patentable for the same reasons set forth above with respect to claim 13 and further that, as stated above, claim 15 recites that the user exchangeable cover part comprises an identification means, which as discussed above, is different than the identification function being contained on the circuit board 46 of Andrews.

Claims 6-8 stand rejected under 35 U.S.C. §103 as being unpatentable over Andrews. This ground of rejection is traversed with respect to newly submitted claims 17-19 which correspond to claims 6-8. Claims 17-19 are patentable for the same reasons set forth above with respect to claim 15.

Claims 3 and 10 stand rejected under 35 U.S.C. §103 as being unpatentable over Andrews in view of United States Patent 5,848,152 (Slipy et al.). These grounds are traversed for the following reasons.

Slipy et al. has been cited for disclosing a method where an operation states is a frequency mode for directing an electrical representation of a ringing signal to the electrical circuitry for providing an illumination effect. Slipy et al. did not cure the deficiencies noted above with respect to the discussion of the rejection of independent claims.

In view of the foregoing amendments and remarks it is submitted that each of the claims in the application is in condition for allowance. Accordingly, early allowance thereof is respectfully requested.

To the extent necessary, Applicants petition for an extension of time under 37 CFR §1.136. Please charge any shortage in the fees due in connection with the filing of this paper, including extension of time fees, to Deposit Account No. 01-2135 (Case No. 1030.41310X00) and please credit any excess fees to such deposit account.

Respectfully submitted,

**A functional cover for use with a wireless terminal.**Background of the Invention

5 The invention relates to a functional cover for use with a wireless terminal, such as a cellular phone. Such covers includes functionality that is implemented by adding electronics to the cover. The invention furthermore relates to the mechanical and the electrical interface between a functional cover and a wireless terminal.

10 Summary of the Invention

According to a first aspect of the invention there is provided a method for operating ~~an electric~~ electrical circuitry included in an exchangeable cover part for supporting a user interface of ~~said the~~ wireless terminal. The wireless communication terminal and ~~said the~~ user exchangeable cover part are  
15 electrically interconnected by means of a electrical connector, and the method includes identification of the type of ~~said the~~ user exchangeable cover part, and operating of the electric circuitry of ~~said the~~ user exchangeable cover part in dependence of the identification of user exchangeable cover part. Hereby the wireless terminal is able to identify the type of the cover in a booting  
20 routine and afterwards operate the cover according to this. The cover may have special illumination ~~effect~~ effects, special game keys, special memories for playing music or playing games.

Preferably the connector has a plurality of pins, and at least one of ~~said the~~  
25 connector pins is operated in an identification state for sensing a resistor value included in the identification means, and afterwards in an operation state for operating the electric circuitry of ~~said the~~ user exchangeable cover part.

30 According to a preferred embodiment of the invention, the operation state is a frequency mode for directing an electrical representation of a ringing signal to

the electric circuitry for providing an illumination effect following the ringing signal.

According to a further aspect, the invention relates to wireless communication terminal having an user exchangeable cover part, wherein the wireless communication terminal and user exchangeable cover part are electrically interconnected by means of a electrical connector. The user exchangeable cover part comprises identification means, and an electric circuitry for supporting a user interface of the wireless terminal. The wireless terminal identifies the user exchangeable cover part by detecting the identification means; and operates the electric circuitry of the user exchangeable cover part in dependence of the identification of user exchangeable cover part.

~~Preferably~~Preferably, the connector includes a plurality of connector pins arranged in line an in equal distance. Advantageously, the connector pins are arranged at the rear side of the cover part. According to a preferred embodiment of the invention, the number of connector pins is three. According to a further embodiment of the invention, the number of connector pins is five.

Preferably, at least one of ~~said the~~ connector pins is operated in an identification state for sensing a resistor value included in the identification means, and afterwards in an operation state for operating the electric circuitry of ~~said the~~ user exchangeable cover part.

In one implementation of the invention, the operation state is a frequency mode for directing an electrical representation of a ringing signal to the electric circuitry for providing an illumination effect ~~synchronised~~synchronized with the ringing signal.

According to a further aspect of the invention there is provided an user exchangeable cover for ~~releaseable~~releasable attachment to a wireless

communication terminal, the user exchangeable cover has an electrical connector part for being electrically connected the wireless communication terminal in attached position. The user exchangeable cover comprises identification means, and an electric circuitry for supporting a user interface of the wireless terminal. The user exchangeable is adapted to allow the wireless terminal to ~~operates~~operate the electric circuitry of the user exchangeable cover part in dependence of the identification of user exchangeable cover part.

#### 10 ~~Brief Description of the Drawing~~Brief Description of the Drawings

For a better understanding of the present invention and to understand how the same may be brought into effect reference will now be made, by way of example only, to accompanying drawings, in which: -

15 Fig. 1 schematically illustrates a preferred embodiment of a wireless telephone according to the invention.

Fig. 2 schematically illustrates a functional front cover for the wireless telephone shown in ~~fig~~Fig. 1.

20

Fig. 3 schematically shows the essential parts of a wireless telephone for communication with ~~e-g~~for example a cellular network.

25 Fig. 4 shows electrical connection between the main block of a wireless telephone and a functional front cover according to preferred embodiments of the invention.

Fig. 5 shows the connection pad for connecting the wireless telephone and a functional front cover according to the preferred embodiment of the invention.

30

Fig. 6 shows the preferred embodiment for the connector part mounted in the functional cover according to the preferred embodiment of the invention.

Fig. 7 shows schematically in partial cross section the connector part connecting the main block of a wireless telephone and a functional front cover according to the preferred embodiments of the invention.

5

Fig. 8 shows a flow chart illustrating the booting and mode selection procedure according to the preferred embodiment of the invention.

#### Detailed Description of the invention

10 Fig. 1 shows a preferred embodiment of a wireless terminal, such as a cellular phone1, which comprises a user interface having a keypad 2, a display 3, an on/off button 4, a speaker 5 (only openings are shown), and a microphone 6 (only openings are shown).

15 According to the preferred embodiment of the invention, the keypad 2 has a first group 7 of keys as alphanumeric keys, two soft keys 8, and a scroll-key 10 (up/down) for moving a cursor in the display. Furthermore the keypad includes two call-handling keys 9 for initiating and terminating calls. The present functionality of the soft keys 8 is shown in a separate field in the  
20 bottom of the display 3 just above the soft keys 8.

The cellular phone1 has an exchangeable functional front cover 25. An exchangeable front cover is intended to be ~~changes~~changed by the user himself without use of tools. Such an exchangeable front cover is disclosed in  
25 US patent application serial number 09/503595 filed by the applicant and this disclosure is hereby incorporated by reference. Fig. 2 shows the exchangeable functional front cover 25 according to the invention.

Fig. 23 schematically shows the most important parts of a preferred  
30 embodiment of the phone, ~~said~~the parts being essential to the understanding of the invention. A processor 18, which supports the GSM terminal software,

also controls the communication with the network via the transmitter/receiver circuit 19 and an antenna 20.

The microphone 6 transforms the users speech into analogue-analog signals;   
5 with the signals formed thereby ~~are-being~~ A/D converted in an A/D converter (not shown) before the speech is encoded in an audio part 14. The encoded speech signal is transferred to the processor 18. The processor 18 also forms the interface to a RAM memory 17a and a Flash ROM memory 17b, a SIM card 16, the display 3 and the keypad 2 (as well as data, power supply, etc.).   
10 The audio part 14 speech-decodes the signal, which is transferred from the processor 18 to the earpiece 5 via a D/A converter (not shown).

Furthermore a clock generator 24 supplies a clock signal to the processor 18. The processor 18 is via a three or five wire bus and a connector 41, 42, 44   
15 connected to electronics 46 in the functional cover 25.

A functional cover 25 is a cover for a wireless terminal 1, which includes functionality that is implemented by adding electronics 46 to the cover 25. To give some examples, it may include an application reacting ~~e-g.~~ for example to   
20 the power supply or ringing tone. It can also be an application that provides input to the phone (~~e-g.~~ for example a touch pad).

The interface between the functional cover and the phone will be ~~describes~~ described. Five different modes will be introduced, out of which   
25 three are very simple and can be used for ~~e-g.~~ example sensor applications. The remaining two are the generic asynchronous serial bus and a mode based on a synchronous data protocol.

The objective of the invention is not to provide a full ~~specify~~ specification of all   
30 the different operation modes, but to allow functional covers and transceivers to interact even through all the modes are not supported by both parts.

According to the preferred embodiment of the invention, the connector includes for three connector pins, a positive power supply voltage pin ( $V_{DD}$ ), a negative power supply voltage pin ( $V_{SS}$ ), and a Cover Type Indicator pin (CTI).

- 5 Preferably the CTI-pin (Cover Type Indicator) is a bi-directional and bi-mode (analogue/digital) signal pin. The CTI-pin is used for a frequency mode, a PWM-mode and a CTI-mode.

- According to an alternative embodiment of the invention the connector  
10 includes five connector pins. As for Like the first embodiment, the connector includes a positive power supply voltage pin ( $V_{DD}$ ), a negative power supply voltage pin ( $V_{SS}$ ), and a Cover Type Indicator pin (CTI). Furthermore the connector includes a Data Signal pin and a Clock Signal pin.

- 15 The Data Signal pin is used for asynchronous data in data mode and in a synchronous data mode. The protocol for the synchronous data mode may be according to the I2C-Bus Specification, version 2.1, January 2000. The Clock Signal pin is used for the clock in synchronous data mode.

Pin	Output type	Description	Communication direction
Vdd		Power supply	Transceiver to Functional cover
Vss		Ground	Transceiver to Functional cover
CTI	Analogue	Frequency output	Transceiver to Functional cover
	Digital	PWM output	Transceiver to Functional cover
	Analogue	Cover Type Indicator	Functional cover to Transceiver
	Digital	PWM input	Functional cover to Transceiver
Data	Digital	Asynchronous data output	Transceiver to Functional cover
	Digital	Synchronous data output	Transceiver to Functional cover
	Digital	Asynchronous data-input.	Functional cover to Transceiver
	Digital	Synchronous data input	Functional cover to Transceiver
Clock	Digital	Clock output	Transceiver to Functional cover
	Digital	Clock input	Functional cover to Transceiver

20 Table 1 Functional cover interface pins

- According to the invention, a baseband (BB) engine and a functional cover do not have to support all the modes. This means that the physical interface may comprise from three to five pins depending on the number of supported  
25 ~~modes supported mode.~~

If the BB engine supports multiple modes, passive mode is not allowed to effect the active mode. This means for example, that when making the CTI measurement, other pins driving the CTI-pin must have high impedance.

- 5 Furthermore the baseband engine must be able to drive  $R_{CTI}$ .

When the wireless terminal 1 is switched on or the processor 18 detects that a new functional cover has been attached to the transceiver part, a boot sequence is initiated. During the boot sequence, the type of the cover is  
 10 detected via the CTI signal. According to that information, the corresponding data mode is selected and the appropriate power supply level,  $V_{dd}$ , is supplied. An example of the boot sequence and mode determination process is presented in ~~fig~~Fig. 8.

15 First is the power switched on to the phone in step 100. Then ~~is the size of the~~ CTI-resistor,  $R_{CTI}$ , is measured in step 101. If the resistor measurement result in step 102 does not exceed a predetermined value (~~e.g. for example~~ 750 k Ohm), the functional cover is deemed to be attached and a further investigation in order to identify the cover, has to be done. If the resistor  
 20 measurement result in step 102 exceeds the first predetermined value, the functional cover is deemed to present. The booting in step 103 has to be continued with the presumption that the cover does not support the electric interface according to the invention.

25 If the processor 18 in step 104 identifies that the cover is "intelligent" – this means that the cover 25 has an asynchronous or synchronous data interface, further information will be exchanged via the digital interface ~~in step~~ in step 105. The digital interface and the power scheme has to be defined. Hereafter the booting with be continued in step 106.

30

If the cover in step 104 is deemed not to be "intelligent", the CTI-resistor,  $R_{CTI}$ , is compared with a second threshold (e.g. ~~64,964.90~~ 64.90 k\_Ohm) and a third

threshold (e.g. ~~93,4~~93.10 k\_Ohm), the cover 25 is deemed to have passive components only, and these component are powered by the power supply of the wireless terminal 1. The voltage is determined by the processor 18 in step 108 by means of a look up table. The booting is continued in step 109.

5

If the CTI-resistor,  $R_{CTI}$ , is falls ~~without~~outside the interval defined by the second and the third threshold, the cover 25 is deemed to be able to perform other modes as a pulse mode, a PWM mode or a frequency mode. The mode and power scheme is determined by the processor 18 in step 110 by means of a look up table. The booting is continued in step 111.

10

Mode	$R_{CTI}$ value
Synchronous data mode	2.00 kOhm
Asynchronous data mode	6.65 kOhm
PWM data mode	30.90 kOhm
	45.30 kOhm
	64.90 kOhm
CTI data mode	93.10 kOhm
	137.0 kOhm
Freq. data mode	210.0 kOhm
	357.0 kOhm
	750.0 kOhm
NO COVER	$\infty$

Table 2 mode supported in dependence of the impedance  $R_{CTI}$ .

Table 2 above describes the CTI resistor value  $R_{CTI}$  vs. functionality conversion. The whole conversion range ~~according~~accordingly is preferably divided into a predetermined number of different sub-ranges. For the "intelligent" modes (synchronous and asynchronous), only one resistor value has been reserved, since all the needed additional information can be transferred via the interface. For PWM- and CTI-modes, two resistor values

15

are reserved and for the Frequency-mode, four resistor values have been reserved.

5 The power control scheme is based on the CTI-information, which is defined in the table 2. The electrical parameters of the power supply includes the power supply voltage VDD, the output current IDD, ~~The the~~ output impedance ZOUT of the wireless terminal 1, and the power on time and power off time.

#### Data interface Synchronous mode-Mode (Data and Clock pins)

10 The data specification used according to the invention may be a sub set of I2C-bus specification version 2.1 January 2000 by Philips Semiconductors. In the synchronous data mode the data pin is used for transferring data between the wireless terminal 1 and the functional cover 25 – usually under control of the processor 18 and the clock oscillator 24 associated therewith.

15

#### ~~Data interface asynchronous mode (Data pin)~~Data Interface Asynchronous Mode (Data pin)

Data is transferred in the asynchronous data mode may be based on an asynchronous half-duplex signal. The power supply may be in the level of VDD = 2.7V 2.7V with a data rate up to 230 kbps.

20

As well the asynchronous data mode, ~~as the~~ synchronous data mode may be used for loading data from multi-media memory card (MMC) like memories included in the functional cover 25 into the wireless terminal for being handled by means of the processor 18. Such a data connection may be used for loading data from multi-media memory card (MMC) like memories included in the functional cover 25 into the wireless terminal for being handled by means of the processor 18. These data may include, ~~e.g. for example~~ MP3 music files and executable games. ~~Hereby is it~~ has become possible to provide a gaming cover – perhaps having an extra joy-stick whose operation is sensed by the gaming cover and – transferred to the wireless terminal via the data pin. The game may also be run on an extra processor included in the functional cover

25

30

25, but using the display 3 of the wireless terminal 1. Extra UI units as a touch sensitive pad / screen or and extra display may be provided on the functional cover 25 and controlled by the processor 18.

#### 5 PWM data mode (via CTI-pin)

Data is transferred using bi-directional CMOS level PWM-modulated CTI-signal. The power supply may be in the level of  $V_{DD} = 2,7V$ ~~2.7V~~. The pulse signal may have a variable frequency up to 32 kHz. The pulse duty cycle may be varied between 0,01~~0.01~~ and 1. This is an analogue~~-analog~~ signal in digital  
10 format, whereby a sound can easily be transferred ref. buzzer signal.

#### CTI data mode (via CTI-pin)

The type information of the cover is given in the CTI. ~~I.e. that is~~ the processor 18 detects the value of the pull down resistor during the start-up (boot) of the  
15 phone and selects the right data and power interface mode according to the predefined table.

This mode is very applicable for applications that do not need any stimulus from the wireless terminal. A flashlight is a good example on such an  
20 application.

#### Frequency mode (via CTI-pin)

In the frequency mode, the functional cover 25 is controlled with the frequency of the CTI-signal. Amplitude information is not needed. Therefore the driving  
25 signal can be a small analogue~~-analog~~ voltage, which is then amplified in the cover end. The frequency signal may according to the preferred embodiment be variable up to 10 kHz.

This mode can be used to direct a ringing tone to the functional cover 25.  
30 Once there, it can be used as a stimulus, for example driving a "light organ".

- The connector interface may comprise three to five pins and associated pads. The electrical requirements for different signal pins will probably be quite different. The CTI-pin will be used for low where as clock and data for medium bandwidth communication. For high bandwidth communication something more sophisticated is needed. As a result, the connector has to be designed according to ~~optimising~~ optimizing the connector with regard to performance and cost.

- The interface on the wireless terminal comprises three to five signal pads for interacting with a similar amount of pogo pins 41, which are included in the cover 25.

Pin name	Pin no	A	D	Unit
CTI	1.	4.3	2	mm
V <sub>SS</sub>	2.			
V <sub>DD</sub>	3.			
Data	4.			
Clock	5.			

Table 3 - Pin order and pad sizes

- The order of the pins appears from ~~fig~~ Figs. 4 and 5. The pins 41 are arranged in a line in equal distance, A. The diameter, D, of the five pads 44 is substantially greater than the diameter of the plungers 42 of the pins 41 in order to ensure a reliable connection.
- It shall be noted that the wireless terminal 1 may have five pads 44. If the functional cover does not support the data modes, only three pins 41 are needed, and these three pins 41 engage the pad 44 corresponding to pins no 1-3.
- The connector according to the preferred embodiment of the invention comprises three Pogo-pins 41 (spring-loaded contacts) mounted on a rigid Printed Wiring Board 40.

The pogo-pins 41 are mechanically fixed and soldered on the ~~Printed Wiring Board~~ printed wiring board 42 in order to maintain safe and low resistance contact between phone's main ~~Printed Wiring Board~~ printed wiring board and Functional Cover's ~~functional cover's~~ small rigid ~~Printed Wiring Board~~ printed wiring board 40. A ~~plunger~~ Plunger 42 should travel ~~should be~~ at least 1 mm and the pressure force between plunger and main ~~Printed Wiring Board's~~ printed wiring board's pads should be minimum 25 g for use in a standard wireless terminal. The pad dimensions and spacing are given in table 4-3 above.

10

Pins may advantageously be gold plated and their internal resistance has to be specified according to the application. Preferably the internal resistance does exceed 100 mΩ even after 10000 cycles.

15 Fig. 7 shows the wireless terminal 1 with the front cover 25 lifted. The pads 44 are arranged on the printed wiring board 43 of the terminal. The printed wiring board 43 is covered by a light guide 45 of transparent plastic has openings allowing the connector pins ~~41, 42~~ 41 and 42 to access the pads. The connector pins ~~41, 42~~ 41 and 42 are mounted on a printed wiring board 40.

20

The printed wiring board 40 is mounted on the inner side of the cover 25 by means of snap coupling means 48. On the rear side of the printed wiring board 40, there is provided an electric circuitry including ~~e.g. for example~~ three LED's 47 illuminating respective pipe formed light-guides 49. In the frequency mode an electrical representation of a ringing signal is directed to the electric circuitry for providing an illumination effect following the ringing signal. The light-guides 49 may be illuminated individually in a tempo following the ringing signal. This gives an exciting effect for the user when the functional cover 25 is partly transparent.

25

30 What is claimed is: -

**A functional cover for use with a wireless terminal.****ABSTRACT.**

5 A wireless communication terminal has a user exchangeable ~~covers~~cover part. The wireless communication terminal and user exchangeable cover part are electrically interconnected by means of an electrical connector. The user exchangeable cover part comprises identification means. The user exchangeable cover part has an ~~electric~~electrical circuitry for supporting a user interface of the wireless terminal. The wireless terminal identifies the user exchangeable cover part by detecting the identification means. The wireless terminal operates the ~~electric~~electrical circuitry of the user exchangeable cover part in dependence of the identification of user exchangeable cover part.

15 Fig. 7.
